2.2	VGA Demo Program	8
3	Tools	13
3.1	Assembler	13
3.1.1	Binary Release	14
3.1.2	Building from Source	14
3.2	Debugging	14
3.2.1	Getting OpenOCD	15
4	Nexys 4 DDR Reference Implementation	17
4.1	SoC Peripherals	17
4.2	Required Hardware	17
4.3	Synthesizing the Core	17
5	Reference Index	19
5.1	Raisin64 Instruction Set	19
5.1.1	Overview	19
5.1.2	Instruction Format	19

5.1.3	16-bit formats	20
5.1.3.1	16R - 16-bit Register Format	20
5.1.3.2	16I - 16-bit Immediate Format	20
5.1.3.3	16-bit OpCode Table	20
5.1.4	32/64-bit Formats	21
5.1.4.1	32R - 32-bit Register Format	21
5.1.4.2	32I - 32-bit Immediate Format	21
5.1.4.3	64S - 64-bit Standard Format	21
5.1.4.4	64J - 64-bit Jump Format	22
5.1.4.5	32 and 64-bit Unit/Op Table	22
5.1.5	Instructions	24
5.1.5.1	ADD - Integer Add	24
5.1.5.2	ADDI - Integer Add Immediate	25
5.1.5.3	AND - Bitwise AND	26
5.1.5.4	ANDI - Bitwise AND Immediate	27
5.1.5.5	BEQ - Branch if Equal	28
5.1.5.6	BEQAL - Branch if Equal And Link	29
5.1.5.7	DIV - Integer Divide	30
5.1.5.8	DIVU - Unsigned Integer Divide	31
5.1.5.9	F* - FPU Call	32
5.1.5.10	J - Jump	33
5.1.5.11	JAL - Jump and Link	34
5.1.5.12	JALI - Jump and Link Immediate	35
5.1.5.13	JI - Jump Immediate	36
5.1.5.14	L16 - Load 16-bit	37
5.1.5.15	L16S - Load 16-bit Sign-Extend	38
5.1.5.16	L32 - Load 32-bit	39
5.1.5.17	L32S - Load 32-bit Sign-Extend	40
5.1.5.18	L8 - Load 8-bit	41
5.1.5.19	L8S - Load 8-bit Sign-Extend	42
5.1.5.20	LUI - Load Upper Immediate	43
5.1.5.21	LW - Load 64-bit Word	44
5.1.5.22	MUL - Integer Multiply	45
5.1.5.23	MULU - Unsigned Integer Multiply	46
5.1.5.24	NOR - Bitwise NOR	47
5.1.5.25	NORI - Bitwise NOR Immediate	48
5.1.5.26	OR - Bitwise OR	49
5.1.5.27	ORI - Bitwise OR Immediate	50
5.1.5.28	S16 - Store 16-bit	51
5.1.5.29	S32 - Store 32-bit	52
5.1.5.30	S8 - Store 8-bit	53
5.1.5.31	SGT - Set 1 if Greater Than	54
5.1.5.32	SGTI - Set 1 if Greater Than Immediate	55
5.1.5.33	SGTIU - Set 1 if Greater Than Immediate Unsigned	56
5.1.5.34	SGTU - Set 1 if Greater Than Unsigned	57
5.1.5.35	SLL - Shift Left Logical	58
5.1.5.36	SLLI - Shift Left Logical Immediate	59
5.1.5.37	SLT - Set 1 if Less Than	60
5.1.5.38	SLTI - Set 1 if Less Than Immediate	61
5.1.5.39	SLTIU - Set 1 if Less Than Immediate Unsigned	62
5.1.5.40	SLTU - Set 1 if Less Than Unsigned	63
5.1.5.41	SRA - Shift Right Arithmetic	64
5.1.5.42	SRAI - Shift Right Arithmetic Immediate	65
5.1.5.43	SRL - Shift Right Logical	66

5.1.5.44	SRLI - Shift Right Logical Immediate	67
5.1.5.45	SUB - Integer Subtract	68
5.1.5.46	SUBI - Integer Subtract Immediate	69
5.1.5.47	SW - Store 64-bit Word	70
5.1.5.48	SYSCALL - System Call	71
5.1.5.49	XOR - Bitwise XOR	72
5.1.5.50	XORI - Bitwise XOR Immediate	73
5.2	Verilog Module Index	74
5.2.1	de_badDetect.v	74
5.2.2	de_canonicalize.v	75
5.2.3	de_isa_def.vh	76
5.2.4	ex_advint.v	76
5.2.5	ex_alu.v	78
5.2.6	Raisin64.v	82
5.2.7	rf_reg.v	85
6	Footnotes	87

Raisin64 (*RISC Architecture with In-order Superscalar INterlocked-pipeline*) is a pure 64-bit CPU design created as part of an educational project. Inspired by the architecture of the [MIPS R10000](#) and [POWER3](#), Raisin64 employs multiple specialized pipelines for integer operations, branching, load/store, etc presently using a simplified issue system appropriate for the scope of a semester-long project.

Unlike most superscalar designs, Raisin64 does not re-order instructions or use register renaming¹ but instead provides a larger architectural register file of 63x64-bit registers.

Major features of the Raisin64 include:

Bits 64-bit

Instructions 50 Opcodes (with 16, 32, and 64-bit formats)

Design RISC (Harvard Architecture²)

Type Register-Register

Branching Compare and Branch

Endianness Big

Registers 63 (R0 = 0)

¹ Raisin64 will issue instructions out-of-order assuming subsequent instructions are dependency-free and the appropriate execution unit is available.

² Split-Cache Modified Harvard when *proposed caches and MMU* are introduced.

RAISIN64 CPU

1.1 Overview

The Raisin64 CPU

1.2 Pipeline Stages

1.2.1 Fetch Unit

1.2.2 Decode Unit

1.2.3 Register File

1.2.4 Schedule Unit

1.2.5 Execution Units

1.2.5.1 Integer Unit

1.2.5.2 Advanced Integer Unit

1.2.5.3 Branch Unit

1.2.5.4 Memory Unit

1.2.6 Commit Unit

1.3 Debug Unit

1.4 Proposed Extensions

Future Work

While out-of-scope for the present period of the project, some initial development was done on *Caches*, an *MMU*, and *Interrupt Unit*, primarily to ensure that they can be integrated into the design without significant modification to the processing pipeline.

These extensions will make the processor capable of running a general purpose operating system (such as Linux) without resorting to software emulation of customarily present hardware.

1.4.1 MMU

Nearly all general purpose operating systems depend on a [Memory Management Unit](#) to provide the virtual addressing used by userspace processes¹². The MMU presents each process with an illusory linear address space potentially overlapping with many other processes. Along with the [Translation Lookaside Buffer](#), an MMU critically allows processes to be placed at arbitrary physical addresses (wherever the RAM happens to be free), with pages of that physical memory mapped at whatever virtual addresses the process expects.

In the Raisin64, the MMU also acts as the first point where the instruction and data caches have a unified window into physical memory, making the processor a split-cache Harvard architecture. Beyond the [page tables](#) which are conventionally placed in main memory, the MMU control registers will be present in the machine's memory-map and be accessible in a kernel-mode un-mapped region (that is, the memory addresses used to access the registers will never be mapped by the MMU and will always be passed through without translation).

Proposed MMU Specs:

Page Size 16KB Fixed

VA Width 47-Bits sign-extended

Page Table Three Level (3x 11-bit entries and 15-bit offset)

The virtual addressing scheme takes inspiration from several modern processor designs as a way to constrain the number of legal virtual addresses while not inhibiting the physical address space available to the MMU. While the virtual addresses are 64-bits, bits 63:47 must be sign-extended (i.e. replicated) from bit 46. This breaks the address space into several proposed regions:

Address	Purpose
0xFFFFFFFF_FFFFFFFF - 0xFFFFC000_00000000	Kernel-Mode Mapped
0xFFFFBFFF_FFFFFFFF - 0xFFFF8000_00000000	Kernel-Mode Unmapped
0xFFFF7FFF_FFFFFFFF - 0x00008000_00000000	Invalid
0x00007FFF_FFFFFFFF - 0x00000000_00000000	User-Mode Mapped

The following figure from ARM on the MIPS processor's memory map conveys the general principle of using the kernel-mode unmapped segment to allow access to IO registers (MMU configuration included) which are present at a fixed physical address:

1.4.2 Interrupt Unit

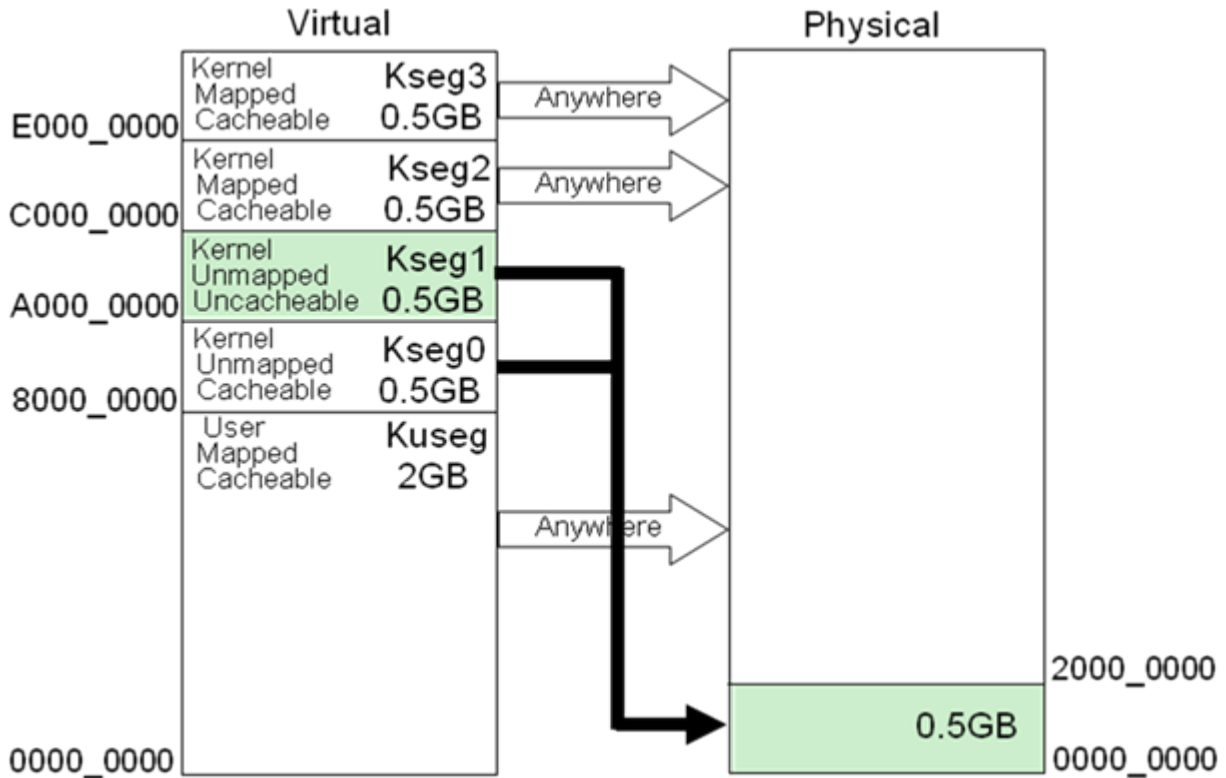

An Interrupt/Exception unit will be necessary to properly implement virtual memory. Attempting to access an un-mapped, evicted, or privileged page from a userspace process should cause the operating system to take over and mitigate the situation (either by loading the page or terminating the process).

The Raisin64's processing pipeline will need some modifications to the [Commit Unit](#) although first steps have already been taken to add a mechanism allowing register and memory writes to be deferred and re-ordered. This can be expanded with program counter tracking information to ensure that the precise location of an interrupt can be recovered and the processor did not commit the pending results of an issued instruction later in the (now aborted) instruction stream.

Fig. 1: From ARM AN235 Section 3.4³

1.4.3 Caches

Relatively simple compared to the MMU or Interrupt Unit, caches will likely have the largest impact on performance of the processor. As the processing pipeline uses a Harvard architecture, the first level of caching is made up of a separate Instruction and Data cache. Each will sit on their respective data ports and provide a small number of highly/fully associative entries that are *virtually indexed and virtually tagged*.

This scheme will necessitate the flushing of the cache on a context switch, but as the only known implementations of the Raisin64 are on FPGAs (without the benefit of hardware content-addressable memory), the caches need to be small regardless and flushing their content on a context-switch will affect only a small number of entries.

Proposed Cache Specs:

L1 Cache Split Instruction/Data

L1 Data Small N-Way/Fully Associative

L1 Instruction Small N-Way/Fully Associative

L1 Tag Scheme Virtually Indexed, Virtually Tagged

L2 Cache Large Unified 2-Way Set Associative

L2 Tag Scheme Physically Indexed, Physically Tagged

While a second level cache between the MMU and main memory may be advantageous, the (comparatively) slow clock rates available from an FPGA but with full speed hardware-accelerated RAM access may eliminate any benefit of another cache.

1.4.4 References

CODE SNIPPETS AND SOFTWARE

Each [instruction](#) page contains an example of how to use that specific opcode which will not be repeated here. Instead, a few simple programs will be presented that work with the [Nexys 4 DDR Reference Implementation](#) demonstrating aspects of the ISA or use of the hardware.

While having a completely different opcode format and compact instruction support, the Raisin64 drew inspiration from MIPS for its instruction set and mnemonics. As a result, several programs I created for a previous academic MIPS design were easily ported to the Raisin64.

2.1 Switch to LED

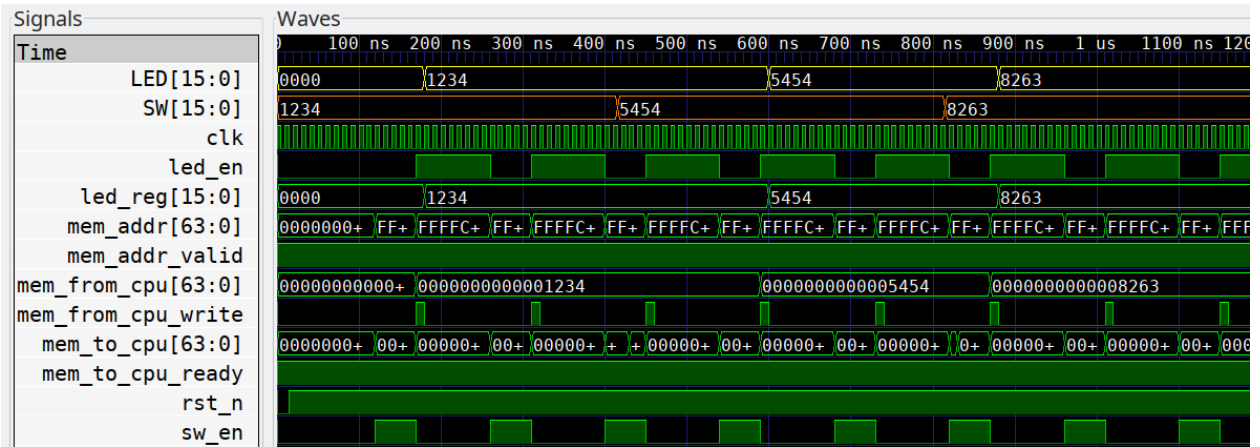

The Switch to LED program is the simplest proof of life for the Nexys 4 DDR board, reading the present position of the switches, and mirroring them onto the array of LEDs located immediately above them.

```
.set SW_LADR, 0x00008000
.set LED_LADR, 0x00004000

.text
#Load the sign-extended upper portion of the IO space in R1
lui $r1, 0xFFFFC000

sw_loop:
ori $r2, $r1, SW_LADR #Load the switch address in R2
lw $r3, ($r2)         #and read into R3
ori $r2, $r1, LED_LADR #Now load LED address into R2
sw $r3, ($r2)         #And store R3 into *R2
ji sw_loop            #Repeat

add $r0, $r0, $r0      #NOP (not a delay slot) TODO Fix for assembler frag_
↪misalignment
```

From a simulation of the external hardware, the LED port can be seen tracking the SW (switch) port soon after it changes. This can be run on the real hardware with the same result:

2.2 VGA Demo Program

As a non-trivial test of the processor, a demo program was created exercising the VGA subsystem of the Nexys 4 DDR board located at 0xFFFFC000_0004xxxx on the data memory bus. In addition to the switch to LED functionality

above, it draws a hello world string and continuously iterates through the character set and color options on the lower half of the display.

The assembly demonstrates the use of a stack, as well as useful GNU assembler tools like defines, macros, data labels, alignment, etc. Also available at: <https://github.com/ChrisPVille/raisin64-nexys4ddr/blob/master/software/demo.S>

```

1  #-----
2  #Macros and defines to make life easier
3
4  .set IO_HADR, 0xFFFFC000
5  .set SW_LADR, 0x00008000
6  .set LED_LADR, 0x00004000
7  .set VGA_LADR, 0x00040000
8
9  .set COLOR_W, 0xF
10 .set COLOR_R, 0xC
11 .set COLOR_G, 0xA
12 .set COLOR_B, 0x9
13 .set COLOR_Y, 0xE
14
15 .set COL, 240

145     addi  $r16, $r16, 1
146     ji    printStr_nextChar
147 printStr_done:
148     fn_exit
149
150 #Sends character to video display
151 # R16: Display Buffer Offset
152 # R17: ASCII Character
153 # R18: Packed Attribute
154 printChar:
155     #We are a leaf function (calls no others).
156     #Don't bother putting ra on the stack as we
157     #won't overwrite it with function calls.
158     slli  $r20, $r18, 8
159     or    $r20, $r20, $r17         #Prepare the packed VGA control word
160     andi  $r20, $r20, 0xFFFF      #and mask it
161
162     #Prepare the base VGA address in R2
163     ori   $r2, $r1, VGA_LADR
164     slli  $r21, $r16, 3            #Shift the buffer "cell" number
165     add   $r2, $r21, $r2          #Add the cell number to the address
166     sw    $r20, ($r2)             #Store the result

```

(continues on next page)

(continued from previous page)

```
167     j     $lr
168
169 .align 11 #Fill 2K
```

Given the long fill period at reset, the simulation is simultaneously un-interesting and overwhelming. Suffice it to say, it leads to a colorful demo.

TOOLS

Being a completely new computer architecture and instruction set, there were no ready-made tools available for assembly, disassembly, linking, debugging, etc. In the spirit of bootstrapping a new system, it was decided early that if the eventual goal is to run a general purpose operating system on the machine, GCC will be required. GCC leverages [binutils](#), a collection of assembly tools, ELF and object file manipulation utilities, as well as a powerful linker.

Using the preliminary instruction set decided early in the semester, binutils was ported to the Raisin64 ISA while the processor was still being designed. Using an existing target (the [moxie](#) as a template, the initial port of binutils was made functional by creating/modifying 26 files across the source.

Future Work

The current Raisin64 GNU Assembler port only constructs the 64-bit version of the instruction set. While the linker, disassembler, and other infrastructure tools should support the smaller instruction words (with some testing done to that effect), the assembler will require significant work outside the scope of the present semester.

While the template architecture was noted for its reasonable size (architecture definitions and assembler were in the many-hundred-line range instead of the tens-of-thousands range for MIPS and X86), the Raisin64 is quite dissimilar being 64-bit with an entirely different instruction scheme. The [actual assembler core](#) was largely rewritten in what became a deep exploration of the binutils architecture.

3.1 Assembler

Being a port of binutils, the Raisin64 assembler should be familiar and comfortable to use for an assembly language programmer supporting the full set of [GNU As](#) features. An effort was made to support MIPS-like syntax with `$r0` or `$zero` register numbering

Named Registers:

Number	Name	Purpose
<code>\$r0</code>	<code>\$zero</code>	Zero Register
<code>\$r62</code>	<code>\$sp</code>	Stack Pointer (no special meaning to processor/convention only)
<code>\$r63</code>	<code>\$lr</code>	Link Register (Destination for JAL/BEQAL /etc.)

The assembler can be invoked as usual for GNU As:

```
raisin64-elf-as <input file> -o <output.elf>
```

which will produce an ELF that can be manipulated with `objdump`, `objcopy`, etc.

An example of the assembly process is in [assemble.sh](#) which takes an input assembly file, produces the assembled ELF, extracts the `.text` and `.data` sections (containing the instruction and data memories respectively), and converts them from hex to ASCII using the `xxd` utility. The result is suitable for the `$readmemh` Verilog commands:

```
raisin64-elf-as $1 -o prog.elf &&
raisin64-elf-objdump -s -j .data prog.elf &&
raisin64-elf-objdump -d -j .text prog.elf &&
raisin64-elf-objcopy -O binary -j .text prog.elf imem.bin &&
raisin64-elf-objcopy -O binary -j .data prog.elf dmem.bin &&
xxd -c 8 -ps imem.bin > imem.hex &&
xxd -c 8 -ps dmem.bin > dmem.hex
```

3.1.1 Binary Release

A binary release of the Raisin64 binutils was prepared, compatible with most 64-bit linux systems: <https://github.com/ChrisPVille/raisin64-binutils/releases>

3.1.2 Building from Source

The Raisin64 port can be obtained here: <https://github.com/ChrisPVille/raisin64-binutils>.

Binutils is mostly free from external dependencies out of necessity, so it should build without too much drama. Just be sure to configure it for the `raisin64-elf` target. i.e.:

```
./configure --target=raisin64-elf --prefix=<install directory>
make -j<threads>
```

3.2 Debugging

As the Raisin64 was designed with a from-scratch JTAG controller I wrote recently (the [JTAGlet](#)), there was no existing support in any tools. Not that JTAG core support would help much given the new ISA, but keeping with the bootstrap theme, a custom configuration script for [OpenOCD](#) was created that uses/misuses the scripting interface to provide communication with the processor's JTAG interface, program the memories, and examine the state of the machine.

Future Work

While the scripting interface was a quick way to support my target, the conventional approach is to write support for targets and JTAG controller in C, releasing a new version of OpenOCD (much like I did with binutils). This will be necessary to support remote debugging (via GDB) and will make future development easier.

The configuration script is too large to repeat here, but is accessible at https://github.com/ChrisPVille/raisin64-cpu/blob/master/support/jtag/raisin64_nodeps_openocd.cfg. It is currently configured for a [Bus Blaster v3](#), but can be easily reconfigured for other JTAG probes.

This script is invoked by the adjacent `programImemDmem.sh` `<imem.hex>` `<optional dmem.hex>` or as:

```
openocd -f "raisin64_nodeps_openocd.cfg" -c "init; raisin64_program <imem.hex>
↪<optional dmem.hex>; exit"
```

The full set of implemented functions are:

Name	Arguments	Purpose
raisin64_halt	none	Halts the CPU (Required before dumping memory)
raisin64_resume	none	Un-Halts the CPU
raisin64_reset	none	Resets the CPU
raisin64_program	<imem.hex> <dmem.hex>	Programs Instruction and Data memory, resetting CPU
raisin64_dump_dmem	<addr> <size>	Dumps the contents of Data memory
raisin64_dump_imem	<addr> <size>	Dumps the contents of Instruction memory

3.2.1 Getting OpenOCD

As the present time, any modern version of OpenOCD can be used along with the script file for the Raisin64. Official releases are at: <http://openocd.org/getting-openocd/> The future Raisin64 version will be located: <https://github.com/ChrisPVille/raisin64-openocd>

4.2 Required Hardware

4.3 Synthesizing the Core

REFERENCE INDEX

5.1 Raisin64 Instruction Set

5.1.1 Overview

The Raisin64's instruction set draws heavily from MIPS with some concepts graciously borrowed from ARM as well. While the programmer's model and instruction set are decoupled from the underlying microarchitecture of the specific implementation, it was nonetheless decided to design the instructions such that a hardwired control unit (see [TODO:ref:Instruction Decode](#)) could process and set the appropriate signals.

Instructions are variable length (16-64) bit, and some have multiple forms like the [ADD Instruction](#). When an instruction has multiple encodings, the opcode is usually the same between the alternate length versions of that instruction, but in all cases the processor expands the 16 and 32-bit versions of the instruction into their canonical 64-bit form, which has a regular encoding. The general instruction formats and opcodes are described below.

But Why?

There is a natural appeal to 64 registers on a 64-bit machine. This means 6 bits are needed in the instruction format to address each register. While 64-bit instructions allow this and efficient loading of immediate values, they waste program space more often than not. Variable length instructions are a good compromise to avoid the size penalty when not necessary.

5.1.2 Instruction Format

There are 6 instruction formats in Raisin64, register and immediate type 16-bit formats (16R and 16I), register and immediate type 32-bit formats (32R and 32I), and a combined register and immediate 64-bit format (64S) as well as a jump format (64J).

Comparing the 16, 32, and 64-bit formats, the smaller instructions contain those instructions which will fit in the reduced number of bits. The larger instruction formats are a super-set of the smaller ones, and whenever an instruction is available in a smaller format, it is available in all larger formats. For example, ADDI is available in 16, 32, and 64-bit instruction size, with the permitted size of the immediate growing as the instruction grows.

The 32 and 64-bit instruction formats share the same Unit/Op numbers, which are effectively the OpCode. The Unit number represents the type of operation while the Op indicates the specific operation requested. This conveniently fits into the first 8 bits of the instruction, making the opcode easier to view and manipulate.

5.1.3 16-bit formats

5.1.3.1 16R - 16-bit Register Format

Size

The 16-bit register format is a compact expression of select instructions operating with one source and one destination register. Instructions normally operating on three registers, such as ADD, instead operate in 2-register mode (i.e. $Rd = Rd + Rs$).

5.1.3.2 16I - 16-bit Immediate Format

Size

The 16-bit immediate format is used only for ADDI and SUBI, allowing for small increment and decrement operations in a compact format.

5.1.3.3 16-bit OpCode Table

OpCode	Type
0 - ADD	16R
1 - SUB	16R
2 - ADDI	16I
3 - SUBI	16I
4 - SYSCALL	16R
5 - J	16R
6 - JAL	16R
7 - Reserved	

5.1.4 32/64-bit Formats

5.1.4.1 32R - 32-bit Register Format

Size Type

All register type instructions in the Raisin64 are available in 32R format. The only exception of this is the F* FPU call, which also uses the immediate field of the 64S format.

5.1.4.2 32I - 32-bit Immediate Format

Size Type

With the exception of JI, JALI, and LUI, all immediate type instructions in the Raisin64 are available in the 32I format with a 12-bit immediate value.

5.1.4.3 64S - 64-bit Standard Format

All register and immediate type instructions (except the immediate type branch and jump instructions) are available in the unified 64S format. When smaller width instructions are encountered by the Raisin64, they are internally expanded into canonical 64S format before being passed onto the rest of the processor. This 64-bit format has space for 4 registers (allowing for instructions like MUL) in addition to 32-bits of immediate data for shifting, bitwise, and ordinary immediate operations).

5.1.4.4 64J - 64-bit Jump Format

A special jump format for large displacement JI and JALI, the 64J format allows for a full 56-bit unsigned jump, more than sufficient to cover the entire virtual address space of the Raisin64.

5.1.4.5 32 and 64-bit Unit/Op Table

R/I	Unit	Op

¹ 64-bit format only² The F* instruction uses the immediate field of 64S to request a specific enumerated service from the FPU. These instructions (and FPU) do not yet exist.

5.1.5 Instructions

5.1.5.1 ADD - Integer Add

Adds registers `Rs1` and `Rs2`, placing the result in `Rd`.

Usage

```
add Rd, Rs1, Rs2
```

Operation

```
Rd = Rs1 + Rs2;  
advance_pc();
```

Encoding

Type 0

Unit 0

Op 0

16-bit Opcode 0x0

32-bit Opcode 0x80

64-bit Opcode 0xC0

5.1.5.2 ADDI - Integer Add Immediate

Adds registers `Rs1` and a sign-extended immediate value, placing the result in `Rd`.

Usage

```
addi Rd, Rs1, imm
```

Operation

```
Rd = Rs1 + sign_extend(imm);  
advance_pc();
```

Encoding

Type 1

Unit 0

Op 0

16-bit Opcode 0x2

32-bit Opcode 0xA0

64-bit Opcode 0xE0

5.1.5.3 AND - Bitwise AND

Bitwise ANDs registers `Rs1` and `Rs2`, placing the result in `Rd`.

Usage

```
and Rd, Rs1, Rs2
```

Operation

```
Rd = Rs1 & Rs2;  
advance_pc();
```

Encoding

Type 0

Unit 3

Op 0

16-bit Opcode NONE

32-bit Opcode 0x8C

64-bit Opcode 0xCC

5.1.5.4 ANDI - Bitwise AND Immediate

Bitwise ANDs register `Rs1` and an immediate value, placing the result in `Rd`.

Usage

```
andi Rd, Rs1, imm
```

Operation

```
Rd = Rs1 & imm;  
advance_pc();
```

Encoding

Type 1

Unit 3

Op 0

16-bit Opcode NONE

32-bit Opcode 0xAC

64-bit Opcode 0xEC

5.1.5.5 BEQ - Branch if Equal

If the `Rs` register is equal to the `Rd` register, the program branches by the signed immediate displacement. As instructions must be aligned to 16-bit boundaries, the immediate value is left shifted by 1 before the jump.

Tip: An unconditional branch can be accomplished by comparing `r0` with itself.

Usage

```
beq Rd, Rs, imm
```

Operation

```
if (Rd == Rs)
    pc = pc + (imm << 1);
else
    advance_pc();
```

Encoding

Type 1

Unit 7

Op 0

16-bit Opcode NONE

32-bit Opcode 0xBC

64-bit Opcode 0xFC

5.1.5.6 BEQAL - Branch if Equal And Link

If the `Rs` register is equal to the `Rd` register, the program branches by the signed immediate displacement. The address of the next linear instruction is placed as a return address in `r63`. As instructions must be aligned to 16-bit boundaries, the immediate value is left shifted by 1 before the jump.

Tip: An unconditional branch can be accomplished by comparing `r0` with itself.

Usage

```
beqal Rd, Rs, imm
```

Operation

```
if (Rd == Rs)
    r63 = next_pc();
    pc = pc + (imm << 1);
else
    advance_pc();
```

Encoding

Type 1

Unit 7

Op 1

16-bit Opcode NONE

32-bit Opcode 0xBD

64-bit Opcode 0xFD

5.1.5.7 DIV - Integer Divide

Divides registers `Rs1` by `Rs2`, and places the quotient in `Rd` and the remainder in `Rd2`, treating operands as 2's complement signed.

Usage

```
div Rd, Rd2, Rs1, Rs2
```

Operation

```
Rd = Rs1 / Rs2;  
Rd2 = Rs1 % Rs2;  
advance_pc();
```

Encoding

Type 0

Unit 4

Op 2

16-bit Opcode NONE

32-bit Opcode 0x92

64-bit Opcode 0xD2

5.1.5.8 DIVU - Unsigned Integer Divide

Divides registers `Rs1` by `Rs2`, and places the quotient in `Rd` and the remainder in `Rd2`, treating operands as unsigned.

Usage

```
div Rd, Rd2, Rs1, Rs2
```

Operation

```
Rd = Rs1 / Rs2;  
Rd2 = Rs1 % Rs2;  
advance_pc();
```

Encoding

Type 0

Unit 4

Op 3

16-bit Opcode NONE

32-bit Opcode 0x93

64-bit Opcode 0xD3

5.1.5.9 F* - FPU Call

Usage

```
todo
```

Operation

```
todo;  
advance_pc();
```

Encoding

Type 0

Unit 7

Op 1

16-bit Opcode NONE

32-bit Opcode NONE

64-bit Opcode 0xDD

5.1.5.10 J - Jump

Unconditional jump to the instruction in `Rs`. As instructions must be aligned to 16-bit boundaries, the immediate value is left shifted by 1 before the jump.

Usage

j Rs

Operation

pc = Rs;

Encoding

Type 0

Unit 7

Op 2

16-bit Opcode 0x5

32-bit Opcode 0x9E

64-bit Opcode 0xDE

5.1.5.11 JAL - Jump and Link

Unconditional jump to the instruction in `Rs`, placing the return address in `r63`. As instructions must be aligned to 16-bit boundaries, the immediate value is left shifted by 1 before the jump.

Usage

```
jal Rs
```

Operation

```
r63 = next_pc();  
pc = Rs;
```

Encoding

Type 0

Unit 7

Op 3

16-bit Opcode 0x6

32-bit Opcode 0x9F

64-bit Opcode 0xDF

5.1.5.12 JALI - Jump and Link Immediate

Unconditional jump to the immediate value, placing the return address in `r63`. The top 8 bits of the jump destination address are taken from the current program counter. As instructions must be aligned to 16-bit boundaries, the immediate value is left shifted by 1 before the jump. Due to the size of the immediate value, JALI is only available in 64J format.

Usage

```
jali imm
```

Operation

```
r63 = pc + 8;  
pc = (pc & 0xff00000000000000) | imm<<1;
```

Encoding

Type 1

Unit 7

Op 3

Op 1

16-bit Opcode 0x3

32-bit Opcode 0xA1

64-bit Opcode 0xE1

5.1.5.47 SW - Store 64-bit Word

Usage

```
todo
```

Operation

```
todo;  
advance_pc();
```

Encoding

Type 1

Unit 6

Op 0

16-bit Opcode NONE

32-bit Opcode 0xB8

64-bit Opcode 0xF8

5.1.5.48 SYSCALL - System Call

Usage

```
todo
```

Operation

```
todo;  
advance_pc();
```

Encoding

Type 0

Unit 7

Op 0

16-bit Opcode 0x4

32-bit Opcode 0x9C

64-bit Opcode 0xDC

5.1.5.49 XOR - Bitwise XOR

Usage

```
todo
```

Operation

```
todo;  
advance_pc();
```

Encoding

Type 0

Unit 3

Op 3

16-bit Opcode NONE

32-bit Opcode 0x8F

64-bit Opcode 0xCF

5.1.5.50 XORI - Bitwise XOR Immediate

Usage

```
todo
```

Operation

```
todo;  
advance_pc();
```

Encoding

Type 1

Unit 3

Op 3

16-bit Opcode NONE

32-bit Opcode 0xAF

64-bit Opcode 0xEF
